Motivation

- Collision detection is a critical technique of user experience in VR.
 - Collision between the users and the objects.
- An user should receive feedbacks while the avatar touches the objects or other users.
 - Be blocked, shaken or the vision feedback.

Current Status

- Online 3D games
 - Some MMORPGs don't handle the collisions between users.
 - Others wraps the characters in cubic or sphere bounds, which makes collision detection much easier.
- VR Application
 - An user interacts with objects using the controllers.
 - There is more complex in multiplayer VR application because of the user experience.

Project Goal

- Evaluate the amount of resources required to perform collision detection between user avatars in a social VR application on cloud server.

1 Introduction

2 **Work Items**

3 Reference

Server

- Set up the server.
- Receives sensor data from clients.
- Performance of collision detection.
- Monitors the usage of each resources.

Client

- Send data to server: position, orientation and body information.
 - Two or Three real users using keyboard and screen to demonstrate the performance.
 - Lots of artificial users to test the scalability.
 - Every user has artificial parts with random path, like arms or legs.
- Receives information from server.
 - The information of other users and objects.
 - collision detection.
- Display

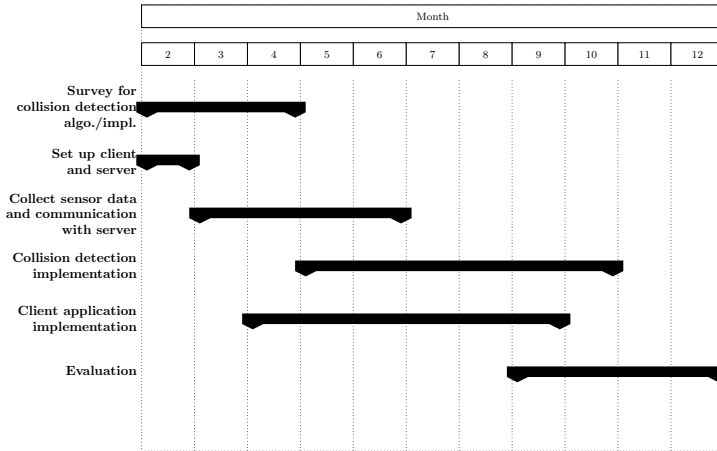

Evaluation

- System scalability
 - Increase the complexity of bounds on avatars and the number of users in limited resources.
 - Resource management.
- System stability
 - Correctness
 - Time consumed.

Expected Deliverables

- A better collision detection algorithm in parallel and distributed system.
- A simple application with GUI by Unity 3D.
- Experimental data.
